Memory Cards and Controllers

David Coombes SCEE

Introduction(1)

- Why are your here listening to me?
- Memory Cards
- Controllers
- Conclusion
- Brief Q.A. session

Some words of wisdom (1)

- Firstly...
 - before, any design work...
 - before any programming...
 - to save effort now and later...

Some words of wisdom(2)

- Obtain, Read and Understand the Q.A. guidelines for each of the territories you want to publish in.
 - Japan is typically the hardest territory to get published in from a European perspective.
 - different video format
 - different typeface/additional characters
 - slightly different QA standards
 - Save yourselves time and money!

SIO System Overview

- Sio transfers (controllers, memory cards)
- All data transfer carried out inside the VSync
- Link Cable is handled differently
- Data transfer must be completed inside the VSync

Memory Cards

- Good
 - Solid State
 - Cool Technology
 - Inexpensive (No need for a complex expensive disk drive)
 - Very simple to use.

Memory Cards

- Bad
 - ► Slow
 - Reputation for being hard to program
 - How many have been sold? Well 60% actually

Access Time

- Speed/Performance
- 4k per second (NTSC) 3.2k per second (PAL)
- Continuous read or write
- CPU load 3.2% (NTSC) 2.7% (PAL)
- Very Slow

Capacity

- > 120K divided into 15 8K slots.
- Max number of files on one card is 15
- File size must be a multiple of 8K

Memory Cards

- File Header
- The header is used by the OSD Card Manager
- It must be correct or else your file will cause problems in this program and may result in data damage either to your file or another applications files.

Memory Card File Header

File Header

```
typedef{
   char Magic[2];
                       //This is always "SC"
                       //Number of icons 0x11=1 0x12=2
   char Type;
   0x12=3
   char BlockEntry;
                       //Number of 8K blocks used
   char Title[64];
                       //Must be in SJIS (32 characters)
   char reserve[28];
                       //Leave this alone
                       //4 bit clut for icons (16*16bits)
   char Clut[32];
                      //3 icons (16*16*4bits)
   char Icon[3][128];
}_CARD
```

Memory Card File Header

- Title Field (Special Note)
- Full-size: Shift-JIS code only, 32 characters (64 bytes)
- If the number of characters is less 32, the character string must be finished with a null character (0x00), or unused space within the 32 characters must be padded with blanks(0x2020).
- The use of ASCII codes is prohibited.

PlayStation

Memory Card Icons

- How do I create my Icons?
 - ► Incbin a 16*16 4 bit tim file
 - Copy the clut and pixel data across into the correct fields.

Special Note on Icons

- Due to a bug in the OSD Memory Card program
 - If your game only uses :1 slot.
 - (only have 1 icon)
 - >:2 slots
 - (have 1 or 2 icons)
 - >:3 or more slots
 - (have 1 or 2 or 3 icons)
- This only applies to the PAL systems

Initialising Memory Cards

- Install memory card system at start of program and do not remove.
- InitCARD does not like to be interrupted.

Detecting the Presence of Memory Cards

- Use services provided by the BIOS
- Use _card_info function
- Interpret the results

Abnormal Processing

- Removal of card during operation / power failure
- ► PlayStation[™] OS provides no user interface for abnormal processing.
- Your application must provide a suitable interface.
- Most of what is required is common sense.

Saving your game

- Required Dialogue
 - Is there a card present?
 - Is it formatted?
 - Is there space?
- Appropriate processing for each (see flow chart in notes)

Accessing memory cards

- Via device driver
 - device name is bu: (backup unit + channel number)
 - Port 1 00 Multi Tap 00 01 02 03
 - Port 2 10 Multi Tap 00 11 12 13

Accessing file structure

Use the firstfile/nextfile functions to get a list of the files and their sizes.

Deleting a memory card file

<u>Example</u>

```
// Delete the file DevConDemo in port 0
```

delete("bu00:DevConDemo");

Creating a memory card file

Example

Important notes on file creation (1)

- The filename is 21 ASCII characters, however...
 - File name is defined by area code i.e. BE for Europe
 - ► 10 digit product code i.e.. SLES_00069
 - It should be terminated with NULL (0x00)
- The remaining characters may be used for personalisation or to support multiple versions.

Important notes on file creation (2)

- Once a file is created its size may not be changed, without deleting and recreating the file. Make sure the file is big enough to start with.
- After creating a file it must be closed before it can be written to.

Writing to a memory card file (Blocking)

- Can only write to a file that already exists
- Must write a multiple of 128 bytes
- Must not write beyond the end of the file

```
fd=open("bu00:DevConDemo",O_WRONLY)
i = write(fd,buff,128);
```

Reading from a memory card file (Blocking)

- Open file in Read only mode
- Must read a multiple of 128 bytes

```
fd=open("bu00:DevConDemo",O_RDONLY);
i = read(fd,buff,128);
```

Writing to a memory card (Non-Blocking)

- Access speed is dependent on the amount written per iteration
- This also affects the frame rate
- Find the right balance for your needs

```
fd=open("bu00:L01",O_WRONLY|O_NO WAIT);
```

```
while((ret = write(fd,data,384))!=0);
```

Reading from a memory card (Non-Blocking)

- Access speed is dependent on the amount read per iteration
- Note: file pointer update in the read function is bugged
- Use Iseek to correct!
- fd=open("bu00:L01",O_RDONLY|O_NOWAIT);
- while((ret = write(fd,data,384))!=0);

When accessing the card

- When reading or writing to the card.....
- Don't omit operation failure checks, for example, check for card removal during a read or write.
- Compress your data to reduce access time
- Consider using checksum for each 128 bytes written and save all data at least twice to back data up

Formatting Cards

- New Cards are supplied unformatted.
- 2 ways of formatting a card.
- Use the _auto_format function. You should not do this inside a final product. This is for testing only.
- Use the format function i.e. format(bu00:)
 - note format is buggy. It always returns a 1 this is no guarantee that the format

Checking format

- Use _card_load() and then test for events again (which is slow) or.....
- Read the first two bytes on the card, if they are "MC" then the card is formatted

Limitations

- Speed of access, the less data you store on the cards the less the game flow will be disrupted by reading/writing to the card
- Cannot play SPU sound whilst accessing a card because both occur inside the VSync and must finish inside the VSync, a time-out will occur.
- This may not be true?

Controllers

- As important as graphics and sound
- The only input to the game
- One device must be suitable for controlling
 - cars, boats, planes, helicopters
 - football teams, robot rabbits, an angry man in a dress....
- Its got to feel right for all these tasks

Controllers

- Standard Controller
- Mouse
- NegCon
- Analogue Device (Joystick)
- Light Gun (Not currently supported)
- Multi Tap (support up to 8 controllers on a single PS)

Standard Controller

- Standard Controller by Sony
- Loads of clones, some approved, some not
- 12 Digital buttons!
- 3d Control system!

Mouse

- Classic two button design from Sony
- Shame there are not more buttons!

NegCon

- Compact Analog device from Namco
- 4 analog channels
- directional button and 3 digital buttons
- Good for driving games.
- Compatible Steering wheel and pedals from MadCatz

Analog device

- Big Analog device from Sony
- 4 analog channels
- ► lots of buttons
- Good for flight sims/ helicopter games /tank games

Gun

- Konami device
- Trigger plus two buttons
- It does get heavy quickly
- No library support at the present

Multi Tap

- Allows four Controllers to be connected to a single port
- Allows up to 8 players simultaneously.
- Allows connection of 8 memory cards.

The Xfiles

- Namco paddle
- Guitar Pick
- Skateboard simulator
- > V.R. headset
- Rowing machines (custom applications)

Controllers

- QA demands that your product:
 - Detect the absence of the correct controller class and respond accordingly
 - Be fully playable with the standard controller
- See the Q.A. Guidelines Document on the BBS for complete details of what is required for Europe

Initialising Controllers (1)

Do not use:

- PadInit(); (This is from libetc)
- PadRead();
- (these functions are used by all of the sample code)

Initialising Controllers (2)

```
Do use:
   InitPAD();
                         (This is from libapi)
   StartPAD();
> Or
   InitTAP();
                         //when using the multi
     tap.
   StartTAP();
                         //use libtap.lib.
      This applies to library all versions up to and
       including 3.4
```

PlayStation

Initialising Memory Cards and Controllers (3)

- Initialise controllers before cards
- See example in notes

Explanation

- buffer1 and buffer2 will be updated every VSync
- Why call ChangeClearPad(0) ?
 - Because StartPad and StartCard both call ChangeClearPad(1); which disables the VSync interrupt handler.
 - You need to turn it back on else your VSync callback functions will never be called

Controller Data Packets

- > CTRLLER.H
- Provides a series of macros which allow simple smooth access to the controller data packets. You can use these in your game or base your own routines on these.
- This file is available from the SCEE BBS and is also on current SCEE release CD

Controllers

- Example of macro usage from ctrller.h
- if the data packet in buffer1 is good and its a standard controller connected then read the controller data.
- if the front left top "shoulder pad" is pressed call the map() function.

Conclusion

- Never underestimate the importance of a good control system
- Make your game easy and fun to play with the standard controller and another controller
- Memory cards give you the ability to increase the depth and complexity of your games.
- Save default settings\preferences.

Therefore

- You should be able to make the best games ever
- ► So go for it!
